目标:用 riscv-pk 来把要执行的程序编译进 linux。编成 boot loader,上板后进 linux 时会自动执行该程序。

1: 安装工具链: riscv64-unknown-elf; riscv64-unknown-linux-gnu

下载代码: https://github.com/OSCPU/riscv-pk

https://github.com/LvNA-system/riscv-rootfs

2: 修改 makefile line79 为香山 linux 库:

git clone --depth 1 -b nanshan https://github.com/OpenXiangShan/riscv-linux.git \$@

```
$(LINUX_REPO_PATH):

mkdir -p $@

phin/echo -e "\033 1;31mBy default, a shallow clone with only 1 commit history is performed, since the commit history is very large.\nThis

git clone --depth 1 -b nanshan https://github.com/OpenXiangShan/riscv-linux.git

$(RFS_ENV) $(MAKE) -C $@ ARCH=riscv emu_defconfig
```

- 3: 设置环境变量 RISCV\_ROOTFS\_HOME 到 riscv-rootfs 路径位置
- 4: 在 riscv-rootfs/apps 内新建一个文件夹, (可参照 hello 文件夹里的内容)放入 C 语言文件, 新建 Makefile, 其中 NAME 为文件夹名称, SRCS 为 C 文件名
- 5: 修改 riscv-rootfs/rootfsimg/initramfs-emu.txt line7 的路径
- 6: 修改 riscv-rootfs/Makefile line3,加入需要运行的程序的文件夹名称,删除不需要运行的程序的文件夹名称。注: busybox 有不明的问题,删除即可
- 7: 修改 riscv-pk/bbl.mk.in line40, 0x60000000 改为 0x80000000
- 8: 在 riscv-pk 下 make, 产生 bbl.bin

```
riscv64-unknown-elf-objcopy -S -O binary --change-addresses -0x80000000 bbl bbl.
bin
make[1]: Leaving directory '/home/dyingman/Desktop/riscv-pk/build'
riscv64-unknown-elf-objcopy --set-section-flags .bss=alloc,contents --set-sectio
n-flags .sbss=alloc,contents -O binary build/bbl build/bbl.bin
riscv64-unknown-elf-objdump -d build/bbl > build/bbl.txt
```
